Congratulations!

You are now the proud owner of a V-Series VFX Guitar Amplifier. These combo amplifiers combine incredible vintage tube sound with 15 outstanding digital effects – giving you a powerful tube amplifier that’s easy to operate yet still produces incredible sounds!

Like all St. Louis Music amplifiers, your VFX is designed by musicians, and built using the finest components available. Extensive testing confirms that this amplifier is the absolute best it can be.

In order to get the most out of your new amplifier, we strongly urge you to read the information contained in this manual before you begin playing.

And Thank You for choosing a V-Series amplifier!

Declaration Of Conformity	
#35, Effective 01-01-2001	
Manufacturer's Name:	SLM Electronics
Production Facility:	11880 Borman Drive, St. Louis, MO 63146, USA
Production Facility:	700 Hwy 202 W, Yellville, AR 72687, USA
Shipping Facility:	1400 Ferguson Ave., St. Louis, MO 63133, USA
Office Facility:	1400 Ferguson Ave., St. Louis, MO 63133, USA
Product Type:	Audio Amplifier
Complies with Standards:	
LVD:	92/31/EEC, 93/68/EEC, & 73/23/EWG
Safety:	EN60065
EMC:	EN55013, EN55020, EN55022, EN61000-3-2, & EN61000-3-3
Supplementary information provided by your local Sales & Services Office or: SLM Electronics - R & D Engineering 1901 Congressional Drive, St Louis, MO 63146, USA Tel.: 314-569-0141, Fax: 314-569-0175	

The Front Panel:

1. Input: Connect your instrument here by means of a shielded signal cable.

2.. Volume: Use this control to adjust the output level of Channel A.

3. Treble: Use this control to adjust the output level of the high frequencies for Channel A. This control provides an adjustment range of 30dB at 10kHz.

4. Mid: Use this control to adjust the output level of the middle frequencies for Channel A. This control provides an adjustment range of 6dB at 600Hz.

5. Bass: Use this control to adjust the output level of the low frequencies for Channel A. This control provides an adjustment range of 30dB at 80Hz.

6. Channel Select: This switch, when depressed, activates Channel B. Channel A is active when the switch is in the out position.

7. Gain: Use this control to adjust the gain for Channel B. With the control towards the counter clockwise position, the gain is low and very little distortion is present. As you rotate the control clockwise the gain increases, producing more overdrive distortion and a higher output volume level.

8. Treble: Use this control to adjust the output level of the high frequencies for Channel B. This control provides an adjustment range of 10dB at 4kHz.

9. Mid: Use this control to adjust the output level of the middle frequencies for Channel B. This control provides an adjustment range of 10dB at 1kHz.

10. Bass: Use this control to adjust the output level of the low frequencies for Channel B. This control provides an adjustment range of 12dB at 100Hz.

11. Level: Use this control to adjust the output level of Channel B.

12. DSP Mode: Use this control to select which of the following digital effects to apply to the signal.

BYPASS	no effect
SMALL REV	small room reverb
MED REV	medium room reverb
LARGE REV	large hall reverb
SLAPBACK	short slapback echo
DELAY 1	short delay w/regen
DELAY/REV 1	short delay w/reverb
DELAY 2	long delay w/regen
DELAY/REV 2	long delay w/reverb
VIBRATO SLOW	slow smooth vibrato
VIBRATO FAST	fast vibrato/tremolo
CHORUS	medium chorus
CHO/REV	medium chorus w/reverb
CHO/REV/DELAY	med cho w/reverb/delay
SLAP CHORUS	slapback echo w/chorus
T-WAH	touch-sensitive wah-wah

13. DSP Level: Use this control to adjust the level of the DSP effect. With the control rotated fully counter clockwise, no effect will be audible. As the control is rotated clockwise the amount of the effect is increased.

14. Presence: Use this control to adjust the overall brightness and punch of the output signal.

15. Lamp: This lamp illuminates when the amplifier is turned on.

16. On/Standby Switch: Use this switch to activate the amplifier after the On/Off Switch (#17) is turned on. **Always turn this switch OFF first and ON last! Turn the On/Off Switch (#17) on at least 30 seconds before turning on the Standby switch.** During short breaks you should turn this switch off and leave the On/Off Switch on. This will help prolong the life of the amplifier's tubes.

17. On/Off Switch: Use this switch to turn the amplifier on and off. **Always turn this switch ON first and OFF last! Turn the Standby switch (#16) on at least 30 seconds after turning on the On/Off Switch.**

The Rear Panel:

18. AC Line Cord (not shown): The grounded power cord should only be plugged into a grounded power outlet that meets all applicable electrical codes and is compatible with the voltage, power, and frequency requirements stated on the rear panel. **Do not attempt to defeat the safety ground connection.**

19. FOOTSWITCH JACK: Use this jack to connect the cable of the footswitch (supplied) for remote control of channel switching and the DSP effect. (Tip = channel select, ring = DSP select.) Refer to the section below for additional information about how the footswitch can be used to save DSP settings from each channel.

20. LINE OUT JACK: Use this jack to send a line level signal from the amplifier to an external amplifier, a mixing console, or the input of an external effect.

21. LINE IN JACK: Use this jack to return the signal from an external effect to the amplifier.

22. EXT. SPEAKER JACK: Use this jack to connect the amplifier to a 16 ohm extension speaker. The internal speaker is not disconnected when this jack is in use. The impedance switch (#23) must be set to the 8 ohm position when a 16 ohm extension speaker is used.

23. IMPEDANCE SWITCH: Use this switch to set the amplifier's output impedance to match the impedance of the speaker(s). The impedance of the speaker(s) inside the amplifier is 16 ohms. The switch is set at the factory to the 16 ohm position. When a 16 ohm extension speaker cabinet is used (see #22), this switch must be set to the 8 ohm position. Use the tip of a small flatblade screwdriver to slide the switch to the proper position.

Impedance switch as seen from below

Using the Footswitch to Save DSP Settings:

The two-button footswitch (supplied) may be used to save two DSP settings for each channel.

- (1) Connect the cable of the footswitch to the Footswitch jack (#19) on the back of the VFX amplifier.
- (2) Click the footswitch buttons until both LEDs are not illuminated. Channel A is now active.
- (3) Select one of the DSP settings - for example, Large Reverb. Click the "EFFECTS A/B" footswitch button (the EFFECTS A/B LED will illuminate). Select another DSP setting - for example, Vibrato Slow. Click the "EFFECTS A/B" footswitch button again (the #EFFECTS A/B LED will go out) and the Large Reverb DSP setting is recalled.

You have now programmed the footswitch to recall two DSP settings for Channel A: Large Reverb (CHANNEL LED not illuminated) and Vibrato Slow (EFFECTS A/B LED illuminated). You may repeat this procedure for Channel B. Click the "CHANNEL" footswitch button (CHANNEL LED illuminated), then repeat step 3 for Channel B using different effects.

Important Information About Tubes and Tube Products:

A Brief History Of The Tube:

In 1883, Edison discovered that electrons would flow from a suspended filament when enclosed in an evacuated lamp. Years later, in 1905, Fleming expanded on Edison's discovery and created the "Fleming Valve". Then, in 1907, Dr. Lee de Forest added a third component – the grid – to the "Fleming's Valve" and the vacuum tube was a fact of life. The door to electronic amplification was now open.

During World War II, data gleaned from their intensive research on the detectors used in radar systems led Bell Telephone Laboratories to the invention of the transistor. This reliable little device gained quick support as the new component for amplification. The death of the vacuum tube seemed imminent as designers, scientists, and engineers reveled in the idea of replacing large, fragile glass tubes with these small, solid-state devices.

However, there were (and still are) many serious listeners who realized that the sound produced by a "transistor" amplifier is significantly different from that produced by a tube amplifier with identical design specifications. They considered the sound produced by these new solid-state devices to be hard, brittle, and lifeless. It was determined that solid-state devices produced a less musical set of harmonics than tubes. When pushed past their limits, they tend to mute the tone and emphasize the distortion.

Tubes, on the other hand, produce a more musical set of harmonics, the intensity of which can be controlled by the player. This characteristic adds warmth and definition to the sound which has become the hallmark of tube amplifiers. When tubes are driven into clipping, the harmonic overtones can be both sweet and pleasing or intense and penetrating, depending on the musician's musical taste and playing technique.

Over the years, application engineers have designed a number of outstanding solid-state amplifiers that sound very, very good. Some use special circuitry which enables them to simulate the distortion characteristics of a tube amplifier. However, the tube amplifier, still held in the highest esteem by many musicians, offers a classic "vintage" sound in a contemporary market.

Tube Types And Usage:

Tube amplifiers are based primarily on two types of tubes – preamplifier tubes and power tubes. The tubes used in preamplifiers (12AX7, 12AU7, 12AT7, etc.) are smaller than the power tubes. These tubes amplify the signal from your instrument and shape the sound. They are inherently microphonic (mechanically pick up and transmit external noises). Since these tubes are used in the critical first stages of a tube amplifier's circuitry, it is very important to use high-quality, low noise/low microphonic tubes for this application. Although tubes of this quality may be difficult to find and typically cost more than "off-the-shelf" tubes, the improvement in performance is worth the investment.

Preamplifier tubes are also used to drive the power tubes. When used in this application, a 12AX7 will produce a more distorted tone than a 12AT7, which produces a clearer, sweeter sound. A 12AU7 is even cleaner and brighter than a 12AT7, giving more definition to the sound. (In some cases it is possible to change the sound by changing the type of preamp and/or driver tubes. When making any modification to your equipment, it is highly recommended that you consult with a qualified service center.)

The power tubes are the largest tubes used in an amplifier. These tubes convert the low-level, conditioned signal from the preamplifier into a level that is sufficient to drive the speakers. There are several types of power tubes available, each of which offers a different performance/sound characteristic. For example, the EL34 power tube produces a great Classic rock sound. When an EL34 is driven into distortion it produces a unique sound ("crunch"). When compared to the EL84 and 6L6, the EL34 distorts more quickly, exhibits a

Important Information About Tubes and Tube Products (continued):

"looser" low-end response and produces more harmonics at mid and high frequencies ("creamier" sound). These differences become more noticeable at higher volumes.

The EL84 and 6L6 tubes produce a big low-end thump and have a very good dynamic range. They offer a more traditional "American Rock" sound. The EL84 and 6V6 tubes produce a creamy sound with nice distortion. On the other hand, the KT88 produces a big low-end but sounds more like an EL34 in the mid and high frequencies.

The 6550 power tubes are more rugged and stay cleaner sounding even at full power. When they do distort, the sound produced is more solid and has a tighter low end; more of a "heavy metal" type distortion with lots of power.

Some tubes are available in matched sets. These tubes have been extensively tested for optimum performance and longevity.

The Nature Of Tubes: Why (And When) To Replace Them:

Tubes are made up of a number of fragile mechanical components that are vacuum-sealed in a glass envelope or bubble. The tube's longevity is based on a number of factors which include how hard and often the amplifier is played, vibration from the speakers, road travel, repeated set up and tear down, etc.

Any time you notice a change in your amplifier's performance, check the tubes first.

If it's been a while since the tubes were replaced and the sound from your amplifier lacks punch, fades in and out, loses highs or lows or produces unusual sounds, the power tubes probably need to be replaced. If your amplifier squeals, makes noise, loses gain, starts to hum, lacks "sensitivity", or feels as if it is working against you, the preamplifier tubes may need to be replaced.

The power tubes are subjected to considerably more stress than the preamplifier tubes. Consequently, they almost always fail/degrade first. If deteriorating power tubes aren't replaced they will ultimately fail.

Depending on the failure mode, they may even cause severe damage to the audio output transformer and/or other components in the amplifier. Replacing the tubes before they fail completely has the potential to save you time, money and unwanted trouble. Since power tubes work together in an amplifier, it is crucial that they (if there is more than one) be replaced by a matched set. If you're on the road a lot, we recommend that you carry a spare matched set of replacement power tubes and their associated driver tubes.

After turning off the power and disconnecting the amplifier from the power source, carefully check the tubes (in bright light) for cracks or white spots inside the glass or any other apparent damage. Then, with the power on, view the tubes in a dark room. Look for preamplifier tubes that do not glow at all or power tubes that glow excessively red.

Whenever you replace the power tube(s):

- Always have the amplifier's bias voltage checked by a qualified service center. Improper bias voltage will cause degradation in performance and possibly damage the tubes and/or the amplifier. (See the section below entitled, "The Importance of Proper Biasing", for more information on this subject).
- We highly recommend that you replace the driver tube(s) as well. The driver tube determines the shape and amplitude of the signal applied to the power tube(s) and has to work almost as hard as the power tube(s).

**Important Information About Tubes and Tube Products (continued):**

You can check your preamplifier tubes for microphonics by turning the amplifier on, turning up the gain and tapping lightly on each tube with the end of a pencil or a chop stick (my favorite). You will be able to hear the tapping through your speakers, which is normal. It is not normal for a tube to ring like a bell after it's tapped. If it does ring then it's microphonic and should be replaced. Remember to use only high quality, low microphonic tubes in the preamplifier section.

Even though power tubes are rarely microphonic, you should check them anyway. The power tubes can be checked for microphonics just like pre-amp tubes.

In the case of very high gain amps, you may be able to reduce the amount of noise generated by simply swapping the preamp tubes around.

The Importance Of Proper Biasing:

For the best performance and longest tube life, proper biasing is imperative. Bias is the negative voltage which is applied to the power tube's control grid to set the level of idle current. We cannot over emphasize the difference in warmth of tone and dynamic response that come with proper biasing. If the bias is set too high (overbiased), the sound from the amp will be distorted at all levels. If the bias is set too low, (under biased) the power tubes will run hot (the plates inside the tubes may glow red due to excessive heat) and the sound from the amplifier will lack power and punch. The excessive heat greatly reduces tube life – from a few days to as little as a few hours in extreme cases. Setting the bias on your amp is like setting the idle on your car. If it's too high or hot it's running away with you and if it's too low or cold it will choke when you step on it.

The bias is adjusted at the factory in accordance with the type of power tube(s) installed in your amplifier. It is important to point out that tubes of the same type and specification typically exhibit different performance characteristics. Consequently, whenever power tubes are replaced, the bias voltage must be checked (unless the amplifier is equipped with "self-biasing circuitry") and readjusted to accommodate the operating parameters of the replacement tubes.

Depending on the model and amplifier type, there may be hum balance controls, trim pots, or bias adjustment controls on its rear panel. However, the bias adjustment should be performed only by qualified service personnel with the proper, calibrated test equipment.

**Important Information About Tubes and Tube Products (continued):****Survival Tips For Tube Amplifiers:**

To prolong tube life, observe these tips and recommendations:

- Match the impedance of your speaker cabinet(s) to your amplifier. Improper impedance matching will contribute to early tube degradation and may cause premature tube failure.
- Make sure the speaker(s) are properly connected prior to turning on the amplifier.
- After playing the amplifier, allow sufficient time for it to properly cool down prior to moving it. A properly cooled amplifier prolongs tube life due to the internal components being less susceptible to the damage caused by vibration.
- Allow the amplifier to warm up to room temperature before turning it on. The heat generated by the tube elements can crack a cold glass housing.
- Replace the output tube(s) before the performance degrades or the tubes fail completely. Replace the tube(s) on a regular basis (at least once per year or as often as every 4 to 6 months if you play long and hard every day).
- Always have the bias checked after replacing the output tubes (unless the amplifier is equipped with "self-biasing circuitry"). This should be done **ONLY** at a qualified service center. Improper biasing could result in the tubes running too hot, which greatly reduces the life of the tubes – or too cold, which results in distorted sound regardless of level settings. Do not play the amplifier if it exhibits these symptoms – get the bias checked/adjusted immediately to prevent tube failure and/or other damage.
- If the locating notch on the base of a power tube breaks off, replace the tube. This significantly reduces the risk of damaging your amplifier by incorrectly inserting the tube.
- Protect the amplifier from dust and moisture. If liquid gets into the amplifier proper, or if the amplifier is dropped or otherwise mechanically abused, have it checked out at an authorized service center before using it.
- Proper maintenance and cleaning in combination with routine checkups by your authorized service center will insure the best performance and longest life from your amplifier.

CAUTION: Tube replacement should be performed only by qualified service personnel who are familiar with the dangers of hazardous voltages that are typically present in tube circuitry.
